## **PARTIE 1 - Introduction**

## 1. INTRODUCTION

La Ville de Rimouski a mandaté la firme André Simard & associés afin d'effectuer une étude portant sur l'impact de l'implantation du lieu d'enfouissement technique de Rimouski sur le niveau de production de biogaz et le dégagement d'odeurs. Conformément aux exigences générales de la Direction des Évaluations environnementales du Ministère de l'Environnement du Québec, l'étude comprend notamment les points suivants:

- Évaluation de la génération du biogaz en fonction du mode d'exploitation du lieu d'enfouissement et du taux d'enfouissement;
- Estimation des débits de biogaz captés et des émissions à l'atmosphère en fonction du scénario d'exploitation du site et du calendrier de mise en place des infrastructures de captage du biogaz;
- Modélisation de la dispersion atmosphérique des composés de soufre réduit totaux;
- Définition d'une procédure de validation des hypothèses de modélisation et des résultats obtenus.

L'étude a été effectuée à l'aide des modèles suivants:

- Logiciel de génération du biogaz *Landfill Air Emission Estimation Model (Landgem)* développé par l'EPA;
- Logiciel de dispersion atmosphérique de type Gaussien ISC3(ST) développé par Trinity Consultant.

Les résultats de l'étude de dispersion atmosphérique sont comparés au critère d'évaluation des impacts reliés au biogaz ainsi qu'aux critères de qualité de l'air du Ministère de l'Environnement.

---

## **PARTIE 2 – Estimation des émissions de biogaz à l'atmosphère**

## 2. ESTIMATION DES ÉMISSIONS DE BIOGAZ À L'ATMOSPHÈRE

### 2.1 HYPOTHÈSES DE MODÉLISATION

Les différentes hypothèses servant d'intrants au modèle de génération et à l'estimation des émissions de biogaz à l'atmosphère sont présentées aux sous-sections suivantes. Ces hypothèses sont basées sur les données transmises par la Ville de Rimouski et la documentation existante typique d'un site d'enfouissement de déchets municipaux en milieu humide.

#### 2.1.1 *Quantité et composition des déchets*

Le lieu d'enfouissement de Rimouski reçoit principalement des déchets municipaux depuis 1980. Le site peut être divisé en trois parties, soit:

- Phase 1 : exploitation de 1980 à 1988, taux d'enfouissement annuel de 35 000 tonnes;
- Phase 2 : exploitation de 1989 à 2003, taux d'enfouissement annuel de 35 000 tonnes;
- Nouveau LET : exploitation de 2004 à 2061, taux d'enfouissement annuel prévu de 42 650 tonnes.

La capacité totale du site existant, opéré de 1980 à 2003, est de 840 000 tonnes. L'implantation du nouveau lieu d'enfouissement technique porterait la capacité totale du site de Rimouski à 3 277 150 tonnes pour une fermeture prévue en 2061.

#### 2.1.2 *Paramètres de modélisation de la génération*

Le niveau de production de biogaz a été défini à l'aide du modèle LANDGEM développé par l'EPA. Ce modèle couramment utilisé dans l'industrie, est un modèle d'ordre 1 impliquant un taux de génération du biogaz décroissant dans le temps. En plus du taux d'enfouissement, deux intrants sont requis par ce modèle, soit la constante de décroissance de la génération du biogaz "k" ( $\text{an}^{-1}$ ) et la production totale de méthane par tonne de déchets "Lo".

Telle que retenue par l'EPA et le Ministère de l'Environnement de l'Ontario, une valeur de "k" égale à 0,04 a été utilisée. Cette valeur serait représentative d'un site d'enfouissement de déchets municipaux recevant plus de 64 cm de précipitation par

année<sup>(1)(2)</sup>. Trois valeurs différentes de "Lo" ont toutefois été utilisées afin de refléter l'évolution du contenu en matière organique dans les déchets:

- Phase 1 : Lo = 230 m<sup>3</sup> CH<sub>4</sub>/tonne de déchets;
- Phase 2 : Lo = 170 m<sup>3</sup> CH<sub>4</sub>/tonne de déchets;
- Nouveau LET : Lo = 160 m<sup>3</sup> CH<sub>4</sub>/tonne de déchets.

Ces valeurs moyennes ont été calculées d'après les valeurs typiques annuelles représentatives de l'évolution de la composition des déchets au Canada depuis 1988<sup>(3)</sup>.

Pour fin d'évaluation du débit de méthane généré, la concentration de ce composé dans le biogaz généré a été fixée à 50% ce qui est typique d'un gaz produit par une dégradation anaérobie stable des déchets dans un site d'enfouissement.

### 2.1.3 Efficacité de captage

Un plan d'arrangement général du réseau de captage du biogaz est présenté à la figure 2-1. Le réseau de captage actif du nouveau LET de Rimouski sera constitué de 48 puits d'extraction verticaux. Ces puits seront installés et raccordés à la station de pompage et de destruction du biogaz au fur et à mesure de la fermeture finale de chacune des cellules. Le tableau 2-1 présente le scénario d'exploitation prévu pour le nouveau LET de Rimouski indiquant pour chaque cellule la date de début de l'exploitation, le tonnage prévu ainsi que la date de mise en place du recouvrement final.

L'efficacité du réseau de captage a été fixée à 85% en tenant compte de la mise en place d'un recouvrement final imperméable, constitué, entre autres, d'une géomembrane, d'une densité de puits élevée afin de permettre un chevauchement des rayons d'influence, ainsi que d'une pression d'aspiration élevée aux têtes de puits.

#### 2.1.4 Estimation des émissions de biogaz à l'atmosphère

Comme des valeurs de "Lo" différentes ont utilisées pour la modélisation de la génération du biogaz pour les phases 1, 2 et le nouveau LET et que le réseau de captage sera mis en opération progressivement au fur et à mesure de la fermeture finale de chaque cellule, l'estimation des débits de biogaz généré et capté ainsi que des débits émis à l'atmosphère pour chaque année, a été effectuée cellule par cellule.

Le niveau d'émissions au niveau du sol a donc été calculé pour chaque année en retranchant les débits captés pour chaque cellule aux débits générés par chaque cellule. Les émissions de biogaz à l'atmosphère ont ensuite été calculées en retranchant 10% du débit non capté aux émissions de biogaz au niveau du sol afin de refléter la dégradation biologique du gaz lors de son passage à travers le sol de recouvrement<sup>(4)</sup>.

## 2.2 RÉSULTATS

Les résultats de la modélisation de la génération du biogaz et de l'estimation des débits de biogaz émis à l'atmosphère sont présentés aux tableaux 2-2 et 2-3. La courbe de génération et de captage du biogaz pour la totalité du site, i.e. incluant l'implantation du nouveau LET, est présentée à la figure 2-2.

Le tableau 2-4 présente la contribution de chacune des parties du site aux émissions de biogaz à l'atmosphère. Les débits maximum de biogaz généré, capté et émis à l'atmosphère obtenus pour chaque secteur suivant le début de l'exploitation du nouveau LET en 2004, sont résumés au tableau 2-5.

Les résultats indiquent que globalement, le maximum de la génération du biogaz se produira en 2061, soit lors de la fermeture du site, avec un débit de 13,36 Mm<sup>3</sup>. Le niveau maximal d'émissions à l'atmosphère sera toutefois obtenu en 2016 avec un débit de 8,61 Mm<sup>3</sup>.

## **PARTIE 3 – Modélisation de la dispersion atmosphérique**

### 3. MODÉLISATION DE LA DISPERSION ATMOSPHÉRIQUE

#### 3.1 MÉTHODOLOGIE

La principale cause d'odeurs identifiée dans le cadre de la présente étude est le dégagement de composés de soufre réduit totaux (SRT) produits par la décomposition des déchets. Le lieu d'enfouissement étant localisé en milieu rural, le bruit de fond a été considéré comme nul.

Les concentrations dans l'air ambiant de SRT à l'extérieur des limites de propriété, sont simulées pour l'année où le taux d'émission de biogaz à l'atmosphère est maximal, soit en 2016 tel qu'indiqué à la section 2.2. Ces concentrations sont déterminées en fonction de données météorologiques locales à l'aide du modèle de dispersion atmosphérique ISC3(ST) qui est un modèle stationnaire et à dispersion Gaussienne, recommandé par l'EPA depuis 1979.

Les sous-sections suivantes présentent les différents paramètres de modélisation utilisés.

##### 3.1.1 Facteur d'émission

Les facteurs d'émission de SRT utilisés comme intrants dans le logiciel ISC3(ST), ont été calculés en fonction de la concentration typique des différents SRT retrouvés dans le biogaz, des surfaces d'enfouissement et des débits de biogaz émis à l'atmosphère correspondant à chaque partie du site pour l'année où le niveau d'émission total est maximal, soit en 2016.

Les concentrations moyennes typiques des SRT retrouvés dans le biogaz, telles que rapportées dans le document AP-42 de l'EPA (voir référence 1), sont les suivantes:

Composé	Concentration volumique (ppmv)	Masse molaire (g/mol)	Concentration massique (mg/m <sup>3</sup> )
Sulfure d'hydrogène	35.5	34.1	49.3
Sulfure de diméthyle	7.82	62.13	19.9
Méthyle mercaptan	2.49	48.11	<u>4.9</u>
SRT			74.1

Le calcul des facteurs d'émission utilisés pour chaque secteur du site est présenté au tableau 3-1.

### 3.1.2 *Caractéristiques des sources d'émissions*

La surface du lieu d'enfouissement a été subdivisée en quatre parties, correspondant à quatre sources de surface distinctes, afin de refléter les facteurs d'émission différents de chaque secteur du site et de mieux représenter la configuration du nouveau LET. Les caractéristiques de ces quatre sources de surface sont présentées au tableau 3-2. La figure 3-1 présente la localisation de ces 4 sources à l'intérieur des limites de propriété.

### 3.1.3 *Caractéristiques de la grille de récepteurs*

L'aire d'étude couvre une superficie de 16 km<sup>2</sup> (voir figure 3-1). Elle est caractérisée par un relief légèrement montagneux au sud et de type rural. Le lieu d'enfouissement se situe à une altitude d'environ 92 mètres en moyenne.

La grille de récepteurs est centrée sur le site d'enfouissement. La grille comprend 441 points et le maillage est de 200 m par 200 m. L'axe des Y est dans la direction nord-sud et l'axe des X dans la direction est-ouest. Les élévations des 441 points de la grille réceptrice ont été déterminées à l'aide de la carte topographique informatisée de la région et sont présentées au tableau 3-3.

La figure 3-1 présente également la localisation des 5 résidences les plus rapprochées du site.

### 3.1.4 *Données météorologiques*

Les données météorologiques nécessaires à la modélisation sont les suivantes:

- Température;
- Vitesse des vents;
- Direction des vents;
- Stabilité;
- Hauteur de mélange.

Les données de température, de vitesse et de direction des vents et de stabilité proviennent de la station météorologique de l'aéroport de Mont-Joli. Les données de hauteur de mélange proviennent de la station de Sept-Iles adaptées aux conditions de la station de Mont-Joli. Les données des années 1996 à 2000 ont été utilisées. Le choix de ces données a été approuvé par M. Richard Leduc du Ministère de l'Environnement du Québec.

**Tableau 3-1 : Calcul des facteurs d'émission - LES et LET de Rimouski**

<b>Émissions maximales à l'atmosphère en 2016</b>	
<b>PHASE 1</b>	
Débit maximal de biogaz émis à l'atmosphère	1,52 Mm <sup>3</sup> /an 0,048 m <sup>3</sup> /s
Concentration de SRT dans le biogaz	74,1 mg/m <sup>3</sup>
Débit maximal de SRT à l'atmosphère	0,0036 g/s
Surface d'enfouissement	126000 m <sup>2</sup>
Facteur d'émission des SRT	2,8346E-08 g/s/m <sup>2</sup>
<b>PHASE 2</b>	
Débit maximal de biogaz émis à l'atmosphère	3,16 Mm <sup>3</sup> /an 0,100 m <sup>3</sup> /s
Concentration de SRT dans le biogaz	74,1 mg/m <sup>3</sup>
Débit maximal de SRT à l'atmosphère	0,0074 g/s
Surface d'enfouissement	148700 m <sup>2</sup>
Facteur d'émission des SRT	4,9933E-08 g/s/m <sup>2</sup>
<b>LET</b>	
Débit maximal de biogaz émis à l'atmosphère	3,94 Mm <sup>3</sup> /an 0,125 m <sup>3</sup> /s
Concentration de SRT dans le biogaz	74,1 mg/m <sup>3</sup>
Débit maximal de SRT à l'atmosphère	0,009 g/s
Surface d'enfouissement	221110 m <sup>2</sup>
Facteur d'émission des SRT	4,187E-08 g/s/m <sup>2</sup>

Sur les cinq ans de données météorologiques, une journée (71<sup>ème</sup> journée de 2000) a été retranchée en raison d'une valeur singulière anormale enregistrée à 6:00 le matin.

La rose des vents caractéristique des données enregistrées à l'aéroport de Mont-Joli est présentée à la figure 3-2. Celle-ci indique que les vents dominants soufflent du sud-ouest.

### 3.1.5 Fichiers d'entrée ISC3(ST)

Les fichiers d'entrée du logiciel de dispersion contiennent la totalité des données présentées aux sous-sections 3.1.1 à 3.1.4. Ceux-ci sont présentés à l'annexe I.

## 3.2 RÉSULTATS

Les concentrations maximales de SRT calculées sur une période de 1 heure sont présentées au tableau 3.4. Les concentrations sont comparées au critère d'évaluation des impacts reliés au biogaz du MENV qui est fixé à  $6 \mu\text{mg}/\text{m}^3$  de SRT dans l'air ambiant à la limite de propriété.

Pour chaque année simulée, les concentrations moyennes maximales horaires obtenues en chaque point de la grille de récepteurs sont présentées à l'annexe II. Les tableaux des 50 plus hautes valeurs simulées sur l'ensemble de la grille de récepteurs pour chaque année de simulation, tels que demandés par le ministère, sont présentés à l'annexe III. Le profil de dispersion pour l'année 1999 est présenté à la figure 3-3. Cette année a été choisie car elle correspond à l'année où la concentration maximale horaire la plus élevée a été enregistrée.

Les résultats indiquent que la concentration moyenne maximale horaire la plus élevée est enregistrée pour l'année 1999 au point (226320, 5364412) avec une valeur de  $7,88 \mu\text{g}/\text{m}^3$  ce qui est égal à 131,3% du critère d'évaluation. L'analyse des 50 plus hautes valeurs obtenues pour chacune des cinq années indique un total de 23 occurrences de dépassement. Ces dépassements sont toutefois tous obtenus à la même date et à la même heure, soit le 5 septembre 1999 à 5:00 AM. Globalement, les dépassements ne sont donc observés que 0.0023% du temps sur une période de 5 ans, soit une heure sur 43 800 heures.

Le tableau 3-5 présente les concentrations maximales horaires enregistrées pour chaque année simulée, aux cinq résidences les plus rapprochées du site. La valeur la plus élevée est obtenue pour l'année 1996 à la résidence R2 avec une concentration de SRT dans l'air ambiant égale à  $5,86 \mu\text{g}/\text{m}^3$  ce qui est équivalent à 97,7% du critère d'évaluation du MENV.

(1) Critère d'évaluation des impacts reliés au biogaz du MENV fixé à 6 ug/m<sup>3</sup>

Le principal impact au niveau de la qualité de l'air, d'un agrandissement ou d'un aménagement d'un lieu d'enfouissement est relié à la détection d'odeurs. C'est pourquoi les composés de soufre réduit totaux sont retenus pour fin de vérification de l'impact au niveau de la qualité de l'air.

En considérant que la concentration de départ des SRT dans le biogaz est de 74,1 mg/m<sup>3</sup> (voir section 3.1.1), la valeur maximale de 7,88 µg/m<sup>3</sup> enregistrée dans l'air ambiant représente un facteur de dilution de plus de 9 400 fois par rapport au biogaz pur.

Le tableau 3-6 présente les composés organiques volatils inclus dans la liste des critères de qualité de l'air du MENV et qui sont typiquement présents dans le biogaz, leur concentration moyenne dans le biogaz telle que répertoriée dans le document AP-42 de l'EPA (voir référence 1), leur concentration probable dans l'air ambiant en appliquant le facteur de dilution obtenu pour les SRT ainsi que les concentrations acceptables définies dans la liste des critères de qualité de l'air du MENV (voir annexe IV).

Les résultats indiquent que les concentrations probables de ces composés dans l'air ambiant sont de plusieurs ordres de grandeur inférieures aux critères fixés par le MENV.

**Tableau 3-6 : Concentrations probables des COV dans l'air ambiant**

## **PARTIE 4 – Validation des modèles**

## 4. VALIDATION DES MODÈLES

Le programme de suivi environnemental proposé pour le LET Rimouski inclura les activités suivantes afin de vérifier la validité des hypothèses utilisées dans le cadre de la présente étude:

- Premièrement, les débits réels de biogaz capté et brûlé seront enregistrés sur une base continue à la station de pompage à l'aide d'un débitmètre thermique massique muni d'un totalisateur;
- Le modèle de génération sera ensuite calibré en fonction des débits réels captés et de l'efficacité de captage du réseau déterminée en fonction de la configuration de celui-ci par rapport aux surfaces d'enfouissement. Cette activité permettra de valider les niveaux estimés d'émission de biogaz à l'atmosphère;
- Par ailleurs, une vérification qualitative des émissions de biogaz à l'atmosphère sera réalisée par un échantillonnage des émissions de méthane à la surface du LES et du LET à l'aide d'un FID. Cette activité sera réalisée après la mise en place du réseau de captage du biogaz afin de vérifier sa performance et d'y apporter des correctifs, s'il y a lieu, dans le but de minimiser les émissions à l'atmosphère;
- Les concentrations réelles de SRT et de composés organiques volatils listés au tableau 3.5 seront déterminées en laboratoire. Pour ce faire, des échantillons de biogaz seront prélevés à la station de pompage dans des canettes passivées et analysés en laboratoire selon la méthode TO-14 de l'EPA.

---

## **PARTIE 5 – Conclusions**

## 5. CONCLUSIONS

Les résultats de la modélisation de la génération du biogaz indiquent que pour la totalité du site (phase 1, phase 2 et nouveau LET) et selon le scénario d'enfouissement retenu, la génération maximale de biogaz se produira en 2061, soit lors de la fermeture du site, avec un débit de 13,36 Mm<sup>3</sup>/an.

Selon le calendrier d'exploitation du lieu d'enfouissement et de mise en place du réseau de captage, le niveau maximal global d'émissions de biogaz à l'atmosphère est toutefois obtenu en 2016 avec un débit de 8,61 Mm<sup>3</sup>/an.

Les résultats de la modélisation de la dispersion atmosphérique indiquent que les concentrations de SRT dans l'air ambiant résultant de l'enfouissement et de la décomposition des déchets au site de Rimouski, dépassent la concentration suggérée par le MENV comme critère d'évaluation des impacts reliés au biogaz, uniquement 0,0023% du temps, soit pendant une heure sur une période de 5 ans,. Les autres critères de qualité de l'air ambiant du Ministère de l'Environnement sont respectés en tout temps.

La concentration maximale horaire de SRT la plus élevée (7,88 µg/m<sup>3</sup>) est obtenue au point (226320, 5364412), ce qui est équivalent à 131,3% du critère d'évaluation de 6 µg/m<sup>3</sup>. Par ailleurs, les résultats obtenus aux résidences les plus rapprochées du site indiquent que la valeur la plus élevée est obtenue à la résidence R2 (Chemin de Lausanne) avec une concentration maximale de SRT dans l'air ambiant égale à 5,86 µg/m<sup>3</sup> ce qui est équivalent à 97,7% de la future norme.

Cyclohexanone	108-94-1	3500	Odeur			9000	RfD
Cyclohexylamine	108-91-8					350	RfD
Decabromodiphenyl ether	1163-19-5					30	RfD
1,4-Dibromobenzène	106-37-6					30	RfD
Dibromochlorométhane	124-48-1					30	RfD
1,2-Dibromo-3- chloropropane	96-12-8					0,2	RfC
1,2-Dibromoéthane	106-93-4					0,005	q*
Dibutyle, phtalate de	84-74-2					0,5	NOAEL/FS
o-Dichlorobenzène	95-50-1	4200	Odeur			160	RfD
p-Dichlorobenzène	106-46-7	730	Odeur			400	RfC
1,2-Dichloroéthane	107-06-2					0,04	q*
1,1-Dichloroéthane	75-34-3					120	NOAEL/FS
1,2-Dichloroéthène	156-60-5					80	LOAEL/FS
Dichloroéthylique, éther	111-44-4					0,003	q*
Dichlorométhane	75-09-2					2	q*
2,4-Dichlorophénol	120-83-2					3	RfD
1,2-Dichloropropane	78-87-5					4	RfC
1,3-Dichloropropène	542-75-6					20	RfC
Di-(2-ethylhexyl), adipate de	103-23-1					400	RfD
Di-(éthyl-2 hexyl), phtalate de	117-81-7					14	RfD
Diméthylamine	124-40-3					2	LOAEL
Diméthylaniline	121-69-7	60	Odeur			3,5	RfD
Diméthylformamide	68-12-2					30	RfC
m-Dinitrobenzène	99-65-0					0,2	RfD
2,4-Dinitrotoluène	121-14-2					3	RfD
Epichlorhydrine	106-89-8					0,8	q*
1,2-Epoxybutane	106-88-7					20	RfC
2-Ethoxyéthanol	110-80-5	800	Odeur			200	RfC
Ethylbenzène	100-41-4					1000	RfC
Ethyle, acétate d'	141-78-6					1600	RfD
Ethyle: chlorure d'	75-00-3	10920	Odeur			10000	RfC
Ethylène glycol	107-21-1	2000	ACGIH STEL/50				
Ethylène, oxyde d'	75-21-8					0,01	q*
Ethylrique, éther	60-29-7		Odeur			350	RfD
Formaldéhyde	50-00-0	37	ACGIH/10

Pyrène	129-00-0					50	RfD
Pyridine	110-86-1	60	Odeur			1,8	RfD
Stoddard, solvant	8052-41-3					60	LOAEL/FS
Styrène, monomère	100-42-5	200	Odeur			1000	RfC
1,2,3,4-Tétrachlorobenzène	634-66-2					10	DJA
1,2,3,5-Tétrachlorobenzène	634-90-2					1,2	DJA
1,2,4,5-Tétrachlorobenzène	95-94-3					0,6	DJA
1,1,1,2-Tétrachloroéthane	630-20-6					0,1	q*
1,1,2,2-Tétrachloroéthane	79-34-5					0,02	q*
Tétrachloroéthène	127-18-4					20	RfD
Tétrachlorométhane	56-23-5					0,07	q*
Toluène	108-88-3		Odeur			400	RfC
1,2,3-Trichlorobenzène	87-61-6					3,5	DJA
1,3,5-Trichlorobenzène	108-70-3					2,7	DJA
1,2,4-Trichlorobenzène	120-82-1		Ontario			18	RfD
1,1,1-Trichloroéthane	71-55-6		NIOSH/100			1100	NOAEL/FS
1,1,2-Trichloroéthane	79-00-5					0,06	q*
Trichloroéthène	79-01-6					2,3	q*
2,4,5-Trichlorophénol	95-95-4					200	RfD
2,4,6-Trichlorophénol	88-06-2					0,3	q*
1,2,3-Trichloropropane	96-18-4					9,3	NOAEL/FS
Triéthylamine	121-44-8					7	RfC
Vanadium	7440-62-2					1	DJA
Vanadium, pentoxyde de (poussière respirable et fumée)	1314-62-1					0,08	LOAEL/FS
Vinyle, acétate de	108-05-4					200	RfC
Vinyle, chlorure de	75-01-4					0,2	q*
Vinylidène, chlorure de	75-35-4					0,02	q*
Xylène (isomères o-, m-, et p-)	1330-20-7	345	Odeur			470	DJA

## NOTES

<sup>1</sup> Critère de gestion MENV

<sup>2</sup> Standard pan-canadien

### Définitions:

**critères** : concentration dans l'air permettant d'éviter l'apparition d'un effet sur la santé ou l'environnement

**critères de gestion ou normes de qualité de l'air** : seuil de concentration basé sur le critère et sur des aspects de faisabilité

**odeur** : seuil d'odeur; la plupart proviennent de AIHA 1989 (American Industrial Hygiene Association)

**NIOSH/100** : recommandation NIOSH divisé par un facteur de sécurité de 100

**RfC** : Référence concentration (EPA IRIS sur [www.epa.gov](http://www.epa.gov))

**RfD** : Référence dose (calculé à partir de la dose de référence; EPA IRIS sur [www.epa.gov](http://www.epa.gov))

**q\*** : concentration équivalent à un risque additionnel de cancer de 1 cas sur 1 million

**NOALE/FS** : NOAEL divisé par un facteur de sécurité (FS)

**LOAEL/FS** : LOAEL divisé par un facteur de sécurité

**DJA** : concentration calculée à partir d'une dose journalière admissible de Santé Canada

**GTLDOQA** : Groupe de travail fédéral-provincial sur les lignes directrices et les objectifs de qualité de l'air

Pour comparer les concentrations modélisées sur 1 heure avec les critères établis sur 15 min ou 1 an, il faut exprimer les concentrations modélisées en concentrations équivalentes sur 15 min, 124 heures et 1 an selon la relation suivante :

$$C_1/C_2 = (T_2/T_1)^{0.2}$$

où

$C_1$  = concentration sur l'intervalle de temps  $t_1$

$C_2$  = concentration sur l'intervalle de temps  $t_2$

$T_1$  = intervalle de temps  $t_1$

$T_2$  = intervalle de temps  $t_2$
