ANNEXE 1 Résultats d'analyse détaillés du biogaz

1. INTRODUCTION

WM a mandaté la firme GENIVAR pour effectuer une caractérisation du biogaz produit au LET de Ste-Nicéphore. Au total, 18 échantillons de biogaz ont été prélevés aux stations de pompage et de destruction du biogaz T4000 et T6000 (9 échantillons par station) pour analyse détaillée en laboratoire.

Les prélèvements ont été effectués du 9 au 11 septembre 2009 par MM. Alexandre Monette et Alain L'Italien de la firme GENIVAR. Les échantillons ont été analysés par le laboratoire de l'Alberta Research Council de Vegreville en Alberta.

2. MÉTHODOLOGIE

2.1 Prélèvement des échantillons

Dix-huit échantillons ont été prélevés sur trois journées consécutives à différents moments de la journée, soit le matin, le midi et en fin de journée, du 9 au 11 septembre 2009, sur une période d'environ 15 minutes chacun.

Les échantillons ont été prélevés consécutivement sur la conduite maîtresse à la sortie des soufflantes des stations de pompage T4000 et T6000 ce qui permet d'obtenir un échantillon composite du biogaz produit par les différentes zones d'enfouissement du LET, soit phase 1, cellules 1@4 et cellules 5@8.

Comme les conduites où ont été pris les échantillons est en pression positive, ceci minimise le risque de dilution. Les échantillons ont été recueillis dans des canettes passivées en acier inoxydable mises sous vide à une pression de - 28" Hg. L'intérieur des cannettes est soumis à un traitement de surface de type SilcoCan. Suite à l'échantillonnage, les cannettes ont immédiatement été retournées au laboratoire par avion pour fin d'analyse à l'intérieur des délais prévus.

2.2 Méthodes d'analyse

Les composés organiques volatils sont analysés selon la méthode TO-15 de l'EPA. Les concentrations des composés sont déterminées par chromatographie en phase gazeuse et spectrométrie de masse (GC/MS). Le système est calibré à l'aide d'un mélange de composés précurseurs d'ozone et du mélange de calibration TO-14 permettant l'analyse d'environ 80 composés cibles. La limite inférieure de détection est de 0,5 ppbv ou moins, la plupart des composés pouvant être détectés à 0,05 ppbv. Tous les autres composés non ciblés apparaissant par chromatographie sont identifiés de façon tentative par leur spectre de masse via une librairie de signatures chimiques.

Les composés soufrés réduits sont séparés par chromatographie en phase gazeuse, détectés et analysés par chimiluminescence (GC/SCD). Le système est calibré à l'aide d'un mélange d'une vingtaine de composés soufrés réduits. La limite inférieure de détection est d'environ 1 ppbv.

3. RÉSULTATS

3.1 Caractérisation du biogaz

Le tableau 3-1 présente les résultats d'analyse obtenus pour les composés inertes, soit CH₄, CO₂, O₂ et N₂. Les résultats ont été corrigés afin de retrancher la portion d'air contenue dans le biogaz capté résultant de l'action des équipements de soutirage, de manière à obtenir la composition du biogaz pur. Par ailleurs, pour chaque évènement d'échantillonnage, les concentrations ont été pondérées en fonction des débits captés à chacune des stations lors du prélèvement, de manière à obtenir la composition du biogaz pur représentatif de la totalité du site.

Les résultats indiquent que le biogaz pur produit à St-Nicéphore est composé de méthane à 60,2% vol et de dioxyde de carbone à 39,8% vol ce qui est typique d'un biogaz produit en phase de méthanogénèse stable.

Les tableaux 3-2 et 3-3 présentent les résultats d'analyse obtenus pour les composés soufrés réduits et les composés organiques volatils. Encore une fois, les résultats ont été corrigés en retranchant la fraction d'air et pondérés en fonction des débits captés à chacune des stations de manière à obtenir la concentration de ces composés dans le biogaz pur et non dans le biogaz dilué et ce, pour la totalité du site.

Les tableaux 3-4 et 3-5 présentent un comparatif entre les concentrations moyennes de SRT et COV répertoriées dans le document AP42 de l'EPA¹ en vigueur ainsi que dans le projet de modification du document AP42 de 2008². Dans ce dernier cas, les concentrations présentées seraient représentatives d'un site dont la majorité des déchets ont été enfouis après 1992.

Au niveau des SRT, on remarque que les concentrations obtenues sont en général beaucoup plus basses pour le biogaz de St-Nicéphore que les valeurs de l'EPA. Par

¹ US EPA (1998) : « Compilation of Air Pollutant Emission Factors » AP-42, Fifth Edition, Vol. 1 Stationary point and area sources, Chapter 2 Solid Waste Disposal. Section 2.4 Municipal Solid Waste Landfills. January 1995, revised in August and November 1998.

² US EPA (2008) : « Compilation of Air Pollutant Emission Factors » AP-42, Fifth Edition, Vol. 1 Stationary point and area sources, Chapter 2 Solid Waste Disposal. Section 2.4 Municipal Solid Waste Landfills. Draft edition, October 2008.

exemple, une concentration moyenne de 3,08 mg/m³ est obtenue pour le H₂S comparativement à des valeurs de 49,3 et 44,5 mg/m³ telles que respectivement répertoriées dans les versions 1998 et 2008 du document AP42.

La concentration totale de SRT dans le biogaz de St-Nicéphore s'élève à 11,27 mg/m³ comparativement à 79,9 mg/m³ pour le document AP42 (1998) et 68,68 mg/m³ pour la révision de 2008.

Pour les composés organiques volatils, on remarque que contrairement à ce qui est rapporté dans le document AP42, les composés suivants n'ont pas été détectés dans le biogaz de St-Nicéphore :

- 1,1,2,2-Tétrachloroéthane;
- 1,1,2-Trichloroéthane;
- 1,2-Dichloropropane;
- Tétrachlorométhane;
- Dichlorométhane;
- Bromure d'éthylène.

En ce qui concerne l'acrylonitrile, ce composé n'a pas été détecté dans le biogaz de St-Nicéphore. Il est à noter que dans la version 2008 du document AP42, ce composé est également rapporté comme étant sous les limites de détection.

Pour les autres composés, les concentrations obtenues pour le biogaz de St-Nicéphore sont en général beaucoup plus basses que les valeurs rapportées dans les 2 versions du document AP42, à l'exception de l'éthylbenzène et du xylène qui présentent des concentrations plus élevées.
